

Functions & Pointers

Derrick

Prototypes

- `int putchar(int);` is known as a prototype.
- The prototype provides the compiler with important information about the return type and parameters.
- When calling a Standard Library function, `#include` the file specified in the man page(s) - this file will contain the prototype
- When calling one of your own functions, write a prototype by hand.
- The function prototype may optionally include variable names. (which are ignored) - `int putchar(int c);`
- Notice that `void` must be used to indicate the absence of a type.

Scope

- C is a block structured language, variables may only be used in functions declaring them.

```
int main(void)
{
    int i = 5, j, k = 2;
    float f = 2.8F, g;
    d = 3.7;
}

void func(int v)
{
    double d, e = 0.0, f;
    i++; g--;
    f = 0.0;
}
```

compiler does not
know about "d"

"i" and "g" not
available here

func's "f" is used,
not main's

Pointers

What?

“A Variable that holds a reference”

(memory address)

- *Already been using pointers (in Java)*

Why?

- *More **efficient** than copying everything.*

How?

- Pointers are declared by using “ * ”.
- Declare an integer: `int i;`
- Declare a pointer to an integer: `int *p;`

Example

```
int      *pi;          /* pi is a pointer to an int */
long int *p;           /* p is a pointer to a long int */
float*    pf;          /* pf is a pointer to a float */
char      c, d, *pc;    /* c and d are a char
                        pc is a pointer to char */
double*   pd, e, f;     /* pd is pointer to a double
                        e and f are double */
char*     start;        /* start is a pointer to a char */
char*     end;          /* end is a pointer to a char */
```

Address? - The “ & ” Operator

- The “ & ” operator (“address of” operator) , generates the address of a variable.
- All variables have addresses except register variables(CPU).

Example

```
char g = 'z';  
int main(void)  
{  
    char c = 'a';  
    char *p;  
  
    p = &c;  
    p = &g;  
  
    return 0;  
}
```

Rules

- Pointers only point to variables of the same type as the pointer has been declared to point to.
 - A pointer to an `int` only point to an `int`.

The “ * ” Operator - Dereference

- The “ * ”, “*dereferencing operator*”, accesses the value that the pointer is pointing to.
 - `int *p;`
 - `p` vs `*p;`
- The value of a pointer may be seen by calling `printf` with `%p` format specifier.
- `printf("The address: %p\n", p);`

Example

```
#include <stdio.h>

char g = 'z';

int main(void)
{
    char c = 'a';
    char *p;

    p = &c;
    printf("%c\n", *p);

    p = &g;
    printf("%c\n", *p);

    return 0;
}
```

print "what p points to"

a
z

NULL

- A special invalid pointer value exists `#defined` in various header files.
 - `stdio.h` , and a few other of Standard headers just in case.
 - `#define NULL 0`
- Mostly defined as zero, but you should never assume this. On some machines zero is a legal pointer and so `NULL` will be defined as something else.

Example

There is a great deal of difference between:

```
int    i = 10, j = 14;  
int    *p = &i;  
int    *q = &j;  
  
*p = *q;
```

and:

```
int    i = 10, j = 14;  
int    *p = &i;  
int    *q = &j;  
  
p = q;
```

Fill in the Gaps

```
int  main(void)
{
    int  i = 10, j = 14, k;
    int  *p = &i;
    int  *q = &j;

    *p += 1;

    p = &k;

    *p = *q;

    p = q;

    *p = *q;

    return 0;
}
```

i
0x2100

j
0x2104

k
0x1208

p
0x120B

q
0x1210

Reminder

- *Call by Value*
- *Call by Reference*

Example (call by value)

```
#include <stdio.h>

void change(int v);

int main(void)
{
    int var = 5;
    change(var);
    printf("main: var = %i\n", var);
    return 0;
}

void change(int v)
{
    v *= 100;
    printf("change: v = %i\n", v);
}
```

the function
was not able
to alter "var"

the function is
able to alter "v"

change: v = 500
main: var = 5

Example (call by reference)

prototype "forces" us to pass a pointer

```
#include <stdio.h>
void change(int* p);
int main(void)
{
    int var = 5;
    change(&var);
    printf("main: var = %i\n", var);
    return 0;
}
void change(int* p)
{
    *p *= 100;
    printf("change: *p = %i\n", *p);
}
```

```
change: *p = 500
main: var = 500
```

Pointers to Pointers

- C allows pointers to any type.
- It is possible to declare a pointer to a pointer

```
#include <stdio.h>

int main(void)
{
    int i = 16;
    int *p = &i;
    int **pp;

    pp = &p;
    printf("%i\n", **pp);

    return 0;
}
```

pp is a "pointer to" a
"pointer to an int"

Review

```
int main(void)
{
    int i = 10, j = 7, k;
    int *p = &i;
    int *q = &j;
    int *pp = &p;

    **pp += 1;

    *pp = &k;

    **pp = *q;

    i = *q***pp;

    i = *q/**pp;    /* headache? */;

    return 0;
}
```
